Lecture 22

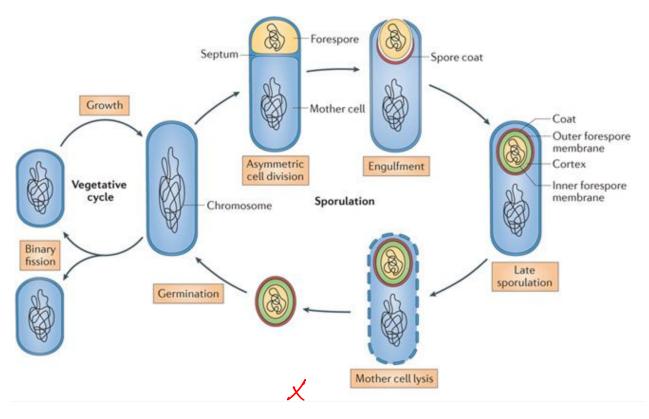

البكتيرا مذول الل بعيزهم إنهم الوصدين اللي بعلوا Endopores

- When faced with harsh environmental conditions, like depletion of any of several nutrients (carbon, nitrogen, or phosphorous). Some gram positive bacteria undergo a cycle of differentiation called sporulation.

 عواد المعالى الم
- Sporulation involves the production of many new structures, enzymes, and metabolites along with the disappearance of many vegetative cell components.
- The spore contains a complete copy of the chromosome, the bare minimum concentrations of essential proteins and ribosomes, and a high concentration of calcium bound to dipicolinic acid
- The **spore** is a resting cell, highly resistant to desiccation, heat, and chemical agents. can exist for centuries as viable spores.
- When returned to favorable nutritional conditions, the spore **germinates** to produce a single vegetative cell.
- The location of the spore within a cell can assist in identification of the bacterium.
- The ultra structure and formation process of spores can vary from one species to another. (<u>exact detailed</u> structure is not exam material).

Copyright © 2006 Pearson Education, Inc., publishing as Benjamin Cummings.

Sporulation begins when a sporangium divides asymmetrically to produce two compartments: the mother cell and the forespore, which are separated by a septum. Next, the mother cell engulfs the forespore, and following membrane fission at the opposite pole of the sporangium, a double-membrane bound forespore is formed. Coat assembly begins just after the initiation of engulfment and continues throughout sporulation. The peptidoglycan cortex between the inner and outer forespore membranes is assembled during late sporulation. In the final step, the mother cell lyses to release a mature spore into the environment. Spores are capable of quickly germinating and resuming vegetative growth in response to nutrients.

Overview

Pathogens that will be discussed this lecture are Spore-Forming Gram-Positive rods

Rods

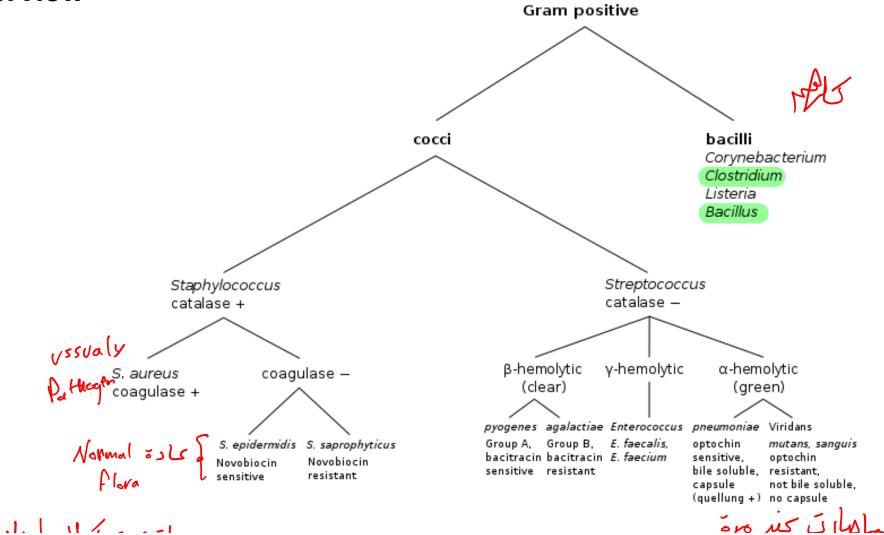

• Bacillus sepcies: The genus Bacillus includes large aerobic, gram-positive rods occurring in chains.

Major pathogens include Bacillus anthracis and Bacillus cereus.

• Clostridium Species: a genus of Gram-positive rods, are obligate anaerobes.

Major pathogens include Clostridium difficile. Clostridium perfringens, Clostridium tetani, Clostridium botulinum

Overview

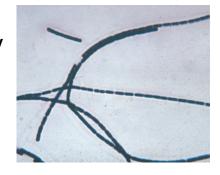

للموى كبيرة هاي

B. anthracis is a large (1 × 3 to 8 μm) organism arranged as single or paired **Gram positive rods** or as long, serpentine chains. Spores are are not seen in clinical specimens.

A bit doubly miles

Anthrax is primarily a disease of herbivores; humans are infected through exposure to contaminated animals or animal products. Exposure can also be part of biological warfare.

Human *B. anthracis* disease is acquired by one of three routes: **inoculation** (Skin infections represent more than 95% of cases), **ingestion**, and **inhalation**.

For information leading to the arrest and conviction of the individual(s) responsible for the mailing of letters containing anthrax to the New York Post, Tom Brokaw at NBC, Senator Tom Daschle and Senator Patrick Leahy:

AS A RESULT OF EXPOSURE TO ANTHRAX, FIVE (5) PEOPLE HAVE DIED.

The person responsible for these deaths...

- Likely has a scientific background/work history which may include a specific familiarity with anthrax
- Has a level of comfort in and around the Trenton, NJ area due to present or prior association

Bacillus anthracis lethol + Westince

Clinical Case 20-1 Inhalation Anthrax

wt

Bush and associates (N Engl J Med 345:1607-1610, 2001) reported the first case of inhalation anthrax in the 2001 bioterrorism attack in the United States. The patient was a 63-year-old man living in Florida who had a 4-day history of fever, myalgias, and malaise without localizing symptoms. His wife brought him to the regional hospital because he awoke from sleep with fever, emesis, and confusion. On physical examination, he had a temperature of 39° C, blood pressure of 150/80 mm Hg, pulse of 110 beats/min, and respiration of 18 breaths/min. No respiratory distress was noted. Treatment was initiated for presumed bacterial meningitis. Basilar infiltrates and a widened mediastinum were noted on the initial chest radiograph. Gram stain of cerebrospinal fluid (CSF) revealed many neutrophils and large gram-positive rods. Anthrax was suspected, and penicillin treatment was initiated. Within 24 hours of admission, CSF and blood cultures were positive for Bacillus anthracis. During the first day of hospitalization, the patient had a grand mal seizure and was intubated. On the second hospital day, hypotension and azotemia developed, with subsequent renal failure. On the third hospital day, refractory hypotension developed and the patient had a fatal cardiac arrest. This patient illustrates the rapidity with which patients with inhalation anthrax can deteriorate despite a rapid diagnosis and appropriate antimicrobial therapy. Although the route of exposure is via the respiratory tract, patients do not develop pneumonia; rather, the abnormal chest radiograph is caused by hemorrhagic mediastinitis.

The major factors responsible for the virulence of *B. anthracis* are the **capsule**, **edema toxin**, **and lethal toxin**. The capsule made of **poly-d-glutamic acid** inhibits phagocytosis of replicating cells. **Edema toxin** is responsible for the fluid accumulation observed in anthrax. **Lethal toxin is** cytotoxic and stimulates macrophages to release proinflammatory cytokines.

The spores germinate in the tissue at the site of entry, and growth of the vegetative organisms results in formation of a gelatinous edema and congestion.

Almost all cases progress to **shock and death within 3 days of initial symptoms** unless anthrax is suspected and treatment is initiated immediately

IN Malaran B 10/22/01 5:30 AM

Inhalation anthrax can be associated with a prolonged latent period (2 months or more), during which the infected patient remains asymptomatic. Spores phagocytosed in the lungs; and transported by the lymphatic drainage to the mediastinal lymph nodes, where germination occurs. Hemorrhagic necrosis and edema of the mediastinum are early manifistations, Sepsis occurs and spread to other organs (GI ulcerations, meningitis) can take place.

B. cereus and other *Bacillus* species are ubiquitous organisms, present in virtually **all environments**.

B. cereus is responsible for two forms of food poisoning: vomiting disease (emetic form) and diarrheal disease (diarrheal form).

المسان عادة pamiting من كادة في

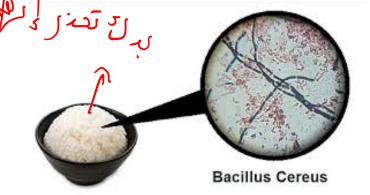

The emetic form of disease results from consumption of contaminated rice. An intoxication caused by ingestion of the enterotoxin, not the bacteria. Thus the incubation period after eating the contaminated rice is short (1 to 6 hours), and the duration of illness is also short (<24 hours).

The diarrheal form of *B. cereus* food poisoning is a true infection of the bacteria in contaminated meat,

vegetables, or sauces. With longer incubation period.

ببخلها من الحبلا

B. cereus ocular infections usually occur after traumatic, penetrating injuries of the eye with a soil-contaminated object.

Spores retain the malachite green dye in this special spore stain, and the vegetative cells are gray or colorless.

Clostridium difficile

obligate anaerobe

Clinical Case 30-1 Clostridium difficile Colitis

Limaye and colleagues (J Clin Microbiol 38:1696, 2000) presented a classic presentation of *C. difficile* disease in a 60-year-old man who received a transplanted liver 5 years previous to his hospital admission for evaluation of crampy abdominal pain and severe diarrhea. Three weeks prior to admission he received a 10-day course of oral trimethoprimsulfamethoxazole for sinusitis. On physical examination, the patient was febrile and had moderate abdominal tenderness. Abdominal computed tomography scan revealed right colon thickening but no abscess. Colonoscopy showed numerous whitish plaques and friable erythematous mucosa consistent with pseudomembranous colitis. Empirical therapy with oral metronidazole and intravenous levofloxacin was initiated. A stool immunoassay for *C. difficile* toxin A was negative, but *C. difficile* toxin was detected by both culture and cytotoxicity assay (demonstration stool filtrate causes cytotoxicity to cell cultures that is neutralized by specific antisera against *C. difficile* toxins). Therapy was changed to oral vancomycin, and the patient responded with resolution of diarrhea and abdominal pain. This is an example of severe C. difficile disease following antibiotic exposure in an immunocompromised patient, with a characteristic presentation of pseudomembranous colitis. The diagnostic problems with immunoassays are well known and have now been replaced by polymerase chain reaction assays that target the toxin genes. Treatment with metronidazole is currently preferred, although vancomycin is an acceptable alternative.

Clostridium difficile

Psvedomemb -- colitis.

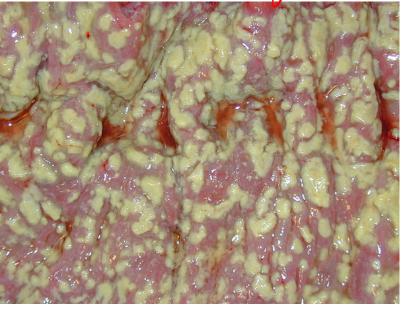

The disease develops in people taking antibiotics, because the drugs alter the normal enteric flora, either permitting overgrowth of أكلب these relatively resistant organisms or making Normal 11 the patient more susceptible to exogenous Plara

acquisition of C. difficile مماد حبوب أفوى افتناد استهافة

Remarkable success with "fecal transplants" has been demonstrated, illustrating the fact that C. difficile does not become established when a healthy enteric population of bacteria is

Colon Up Wing

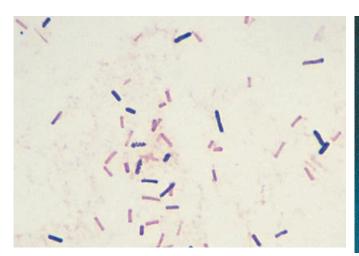

Pseudomembranous colitis is an inflammatory condition of the colon characterized by elevated yellow -white plaques that coalesce to form pseudomembranes on the mucosa.

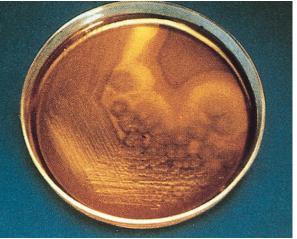

Clostridium perfringens Leuple Leuple La sports & colonies rapid, spread

C. perfringens is a large (0.6 to 2.4×1.3 to $19.0 \mu m$), rectangular, gram-positive rod, with spores rarely observed either in vivo or after in vitro cultivation, an important characteristic that differentiates this species from most other clostridia. Colonies of C. perfringens are also distinctive, hemolysis with their rapid, spreading growth. Theta complete

5 वि दुर्गी उक्तिम

Type A C. perfringens commonly inhabits the intestinal tract of humans and animals and is widely distributed in nature, particularly in soil and water contaminated with feces. Spores are formed under adverse environmental conditions and can survive for prolonged periods. Strains of types B through E do not survive in soil but colonize the intestinal tracts of animals and occasionally humans

A presumptive identification of C. perfringens can be made by detection of a zone of complete hemolysis (caused by the theta toxin) and a wider zone of partial hemolysis (caused by the alpha toxin), combined with the characteristic microscopic morphology.

intoxication

• *C. perfringens* produces **enterotoxin**, The enterotoxin is produced during the phase transition from vegetative cells to spores and is released in the alkaline environment of the small intestine when the cells undergo the terminal stages of spore formation (**sporulation**).

Treatment is usually

debridement and excision,
with amputation necessary
in many cases. Watersoluble antibiotics (such as
penicillin) alone are not
effective because they do
not penetrate ischaemic
muscles sufficiently to be
effective.

Clostridium perfringens

 Spore forming bacteria are ubiquitous in nature and can easily contaminate sharp objects, subsequently causing infections in wounds.

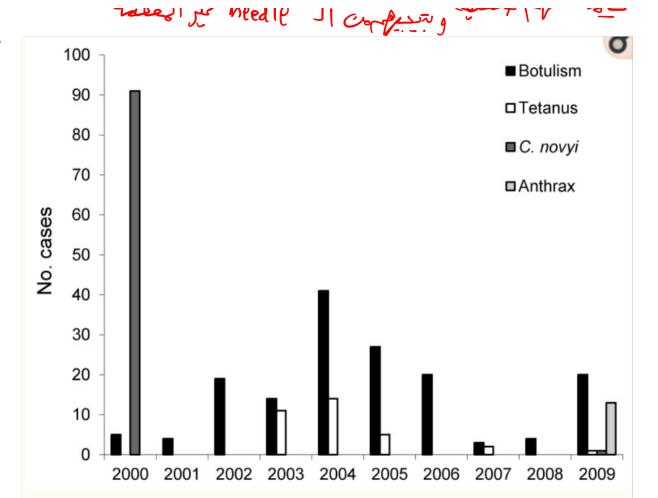

Figure 1

Annual numbers of cases of botulism, tetanus, *Clostridium novyi* infection, and anthrax among persons who inject drugs, England and Scotland, 2000–2009.

Overview

Clinical Case 30-3 Tetanus

The following is a typical history of a patient with tetanus (CDC, MMWR) Morb Mortal Wkly Rep 51:613-615, 2002). An 86-year-old man saw a physician for care of a splinter wound in his right hand, acquired 3 days earlier while gardening. He was not treated with either a tetanus toxoid vaccine or tetanus immune globulin. Seven days later he developed pharyngitis, and after an additional 3 days, he presented to the local hospital with difficulty talking, swallowing, and breathing, and with chest pain and disorientation. He was admitted to the hospital with the diagnosis of stroke. On his fourth hospital day, he had developed neck rigidity and respiratory failure, requiring tracheostomy and mechanical ventilation. He was transferred to the medical intensive care unit, where the clinical diagnosis of tetanus was made. Despite treatment with tetanus toxoid and immune globulin, the patient died 1 month after admission to the hospital. This case illustrates that Clostridium tetani is ubiquitous in soil and can contaminate relatively minor wounds; it also illustrates the unrelenting progression of neurologic disease in untreated patients.

Vaccine foll

Clostridium tetani : spastic paralysis

C. tetani is a large (0.5 to 2 × 2 to 18 μm), motile, spore-forming rod. The organism produces round, terminal spores that give it the appearance of a drumstick. C. tetani is ubiquitous. It is found in fertile soil and transiently colonizes the GI tracts of many animals, including humans.

• C. tetani produces two toxins, an oxygen-labile hemolysin (tetanolysin) and a plasmid-encoded, heat-labile neurotoxin (tetanospasmin).

texins of CNS

neuro Ilgolia

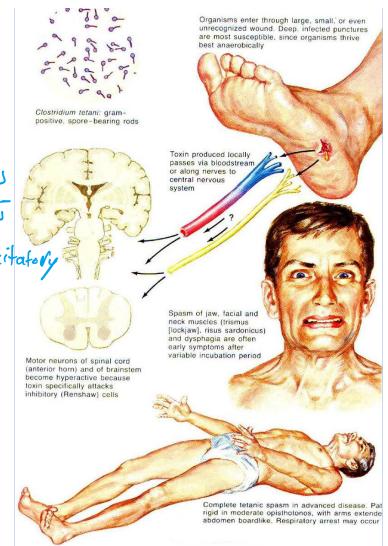

• Tetanospasmin inactivates proteins that

regulate release of the inhibitory

neurotransmitters glycine and gammaaminobutyric acid (GABA). This leads to
unregulated excitatory synaptic activity in the
motor neurons, resulting in spastic paralysis.

• Disease is relatively rare because of the high incidence of **vaccine-induced immunity**.

Clostridium botulinum

Clinical Case 30-4 Foodborne Botulism with Commercial Carrot Juice

يمان

ا لق

في المعلمات

The Centers for Disease Control and Prevention reported an outbreak of foodborne botulism associated with contaminated carrot juice (MMWR) Morb Mortal Wkly Rep 55:1098, 2006). On September 8, 2006, three patients went to a hospital in Washington County, Georgia, with cranial nerve palsies and progressive descending flaccid paralysis resulting in respiratory failure. The patients had shared meals on the previous day. Because botulism was suspected, the patients were treated with botulinum antitoxin. The patients had no progression of their neurologic symptoms, but they remained hospitalized and on ventilators. An investigation determined that the patients had consumed contaminated carrot juice produced by a commercial vendor. Botulinum toxin type A was detected in the serum and stool of all three patients and in leftover carrot juice. An additional patient in Florida was also hospitalized with respiratory failure and descending paralysis after drinking carrot juice sold in Florida. Because carrot juice has a low acid content (pH 6.0), Clostridium botulinum spores can germinate and produce toxin if contaminated juice is left at room temperature.

- The etiologic agents of botulism are a heterogeneous

collection of large (0.6 to 1.4×3.0 to $20.2 \mu m$), fastidious, spore-forming, anaerobic rods. *C. botulinum* is commonly isolated in soil and water samples throughout the world.

و ممكن تدخل من تمزه عي ال

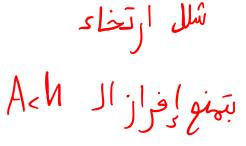

Patients with **foodborne botulism** (most are associated with consumption of home-canned foods) typically become weak and dizzy 1 to 3 days after consuming the contaminated food. Bilateral descending weakness of the peripheral muscles develops in patients with progressive disease (flaccid paralysis), and death is most commonly attributed to respiratory paralysis. و بنطوا کا جرهاز نتمنس و صلی تأدی للوفات
