

Renal Physiology 2

Guyton

Ebaa M Alzayadneh, PhD

Renal Handling of Water and Solutes

	Filtration	reabsorption	excretion
L/day Water	180	179	1
Na+ mmol/day	25,560	25,410	150
Glucose gm/day	180	180	0
Creatinine gm/day	1.8	0	1.8

Renal Handling of Different Substances

Figure 26-10

Effects of size and electrical charge of dextran on filterability by glomerular capillaries.

Figure 26-12

Glomerular Filtration

GFR = 125 ml/min = 180 liters/day

- Plasma volume is filtered 60 times per day
- Glomerular filtrate composition is about the same as plasma, except for large proteins
- Filtration fraction (GFR / Renal Plasma Flow) = 0.2 (i.e. 20% of plasma is filtered)

Clinical Significance of Proteinuria

- Early detection of renal disease in at-risk patients
 - **hypertension**: hypertensive renal disease
 - **diabetes**: diabetic nephropathy
 - **pregnancy**: gestational proteinuric hypertension (pre-eclampsia)
 - **annual “check-up”**: renal disease can be silent
- Assessment and monitoring of known renal disease

Glomerular Filtration

$$\begin{array}{r}

Figure 26-13

Glomerular Filtration Rate (GFR)

- **Filtration Fraction (FF)**= Fraction of blood plasma in the afferent arterioles that becomes filtrate= 16-20%.
- **GFR** =The volume (ml) of fluid filtered through all the corpuscles of both kidneys per minute.
- The volume of fluid filtered daily through all the corpuscles of both kidneys per day = 180 L
- **Hence, GFR**= $180 \text{ L}/24\text{hours} * (1000 \text{ ml}/\text{L})*(1\text{hour}/60 \text{ min})= \mathbf{125 \text{ ml/min (Males)}}$
- For 125ml/min; renal plasma flow = 625ml/min
 $FF * PF=GFR, PF= 125/(20\%)=625 \text{ ml/min}$
- 55% of blood is plasma, so blood flow = 1140ml/min
 $55\% * BF= PF; BF= 625\text{ml/min}/ (55\%)=1140 \text{ ml/min}$
- Renal Blood Flow of 1140 ml/min = (22.8 % of 5 liters) is required to have GFR of 125ml/min.

Clinical Application

- **Edema**
- Some kidney diseases result in a damage of the glomerular Capillaries leading to an increase in their permeability to large proteins .
- Hence, Bowman's capsule colloid pressure will increase significantly leading to drawing more water from plasma to the capsule (i.e more filtered fluid).
- Proteins will be lost in the urine causing deficiency in the blood colloid pressure which worsens the situation, blood volume decreases and interstitial fluids increases causing **edema**.

Regulation of Glomerular Filtration

- Homeostasis of body fluids requires constant GFR by kidneys.
- If the GFR is too high, needed substances cannot be reabsorbed quickly enough and are lost in the urine.
- If the GFR is too low -everything is reabsorbed, including wastes that are normally disposed of.

Determinants of Glomerular Filtration Rate

Normal Values:

GFR = 125 ml/min

Net Filt. Press = 10 mmHg

$K_f = 12.5$ ml/min per mmHg, or
4.2 ml/min per mmHg/ 100gm
(400 x greater than in
many tissues)

Glomerular Capillary Filtration Coefficient (K_f)

- K_f = hydraulic conductivity x surface area

$$K_f = \text{GFR} / \text{net filt pressure}$$

- Normally not highly variable
- Disease that can reduce K_f and GFR
- damage of capillaries, BM thickens,
 - chronic hypertension
 - obesity / diabetes mellitus
 - glomerulonephritis

Glomerular Injury in Chronic Diabetes

Normal glomerulus

Diabetic nephropathy

Bowman's Capsule hydrostatic Pressure (P_B)

- Normally changes as a function of GFR,
not a physiological regulator of GFR
- Increases with Tubular Obstruction
kidney stones
tubular necrosis

Reducing GFR

- Urinary tract obstruction
Prostate hypertrophy/cancer

Factors Influencing Glomerular Capillary Oncotic Pressure (Π_G)

- Arterial Plasma Oncotic Pressure (π_A)

- Filtration Fraction (FF)

$$\begin{aligned} FF &= \text{GFR} / \text{Renal plasma flow} \\ &= 125 / 650 \sim 0.2 \text{ (or 20\%)} \end{aligned}$$

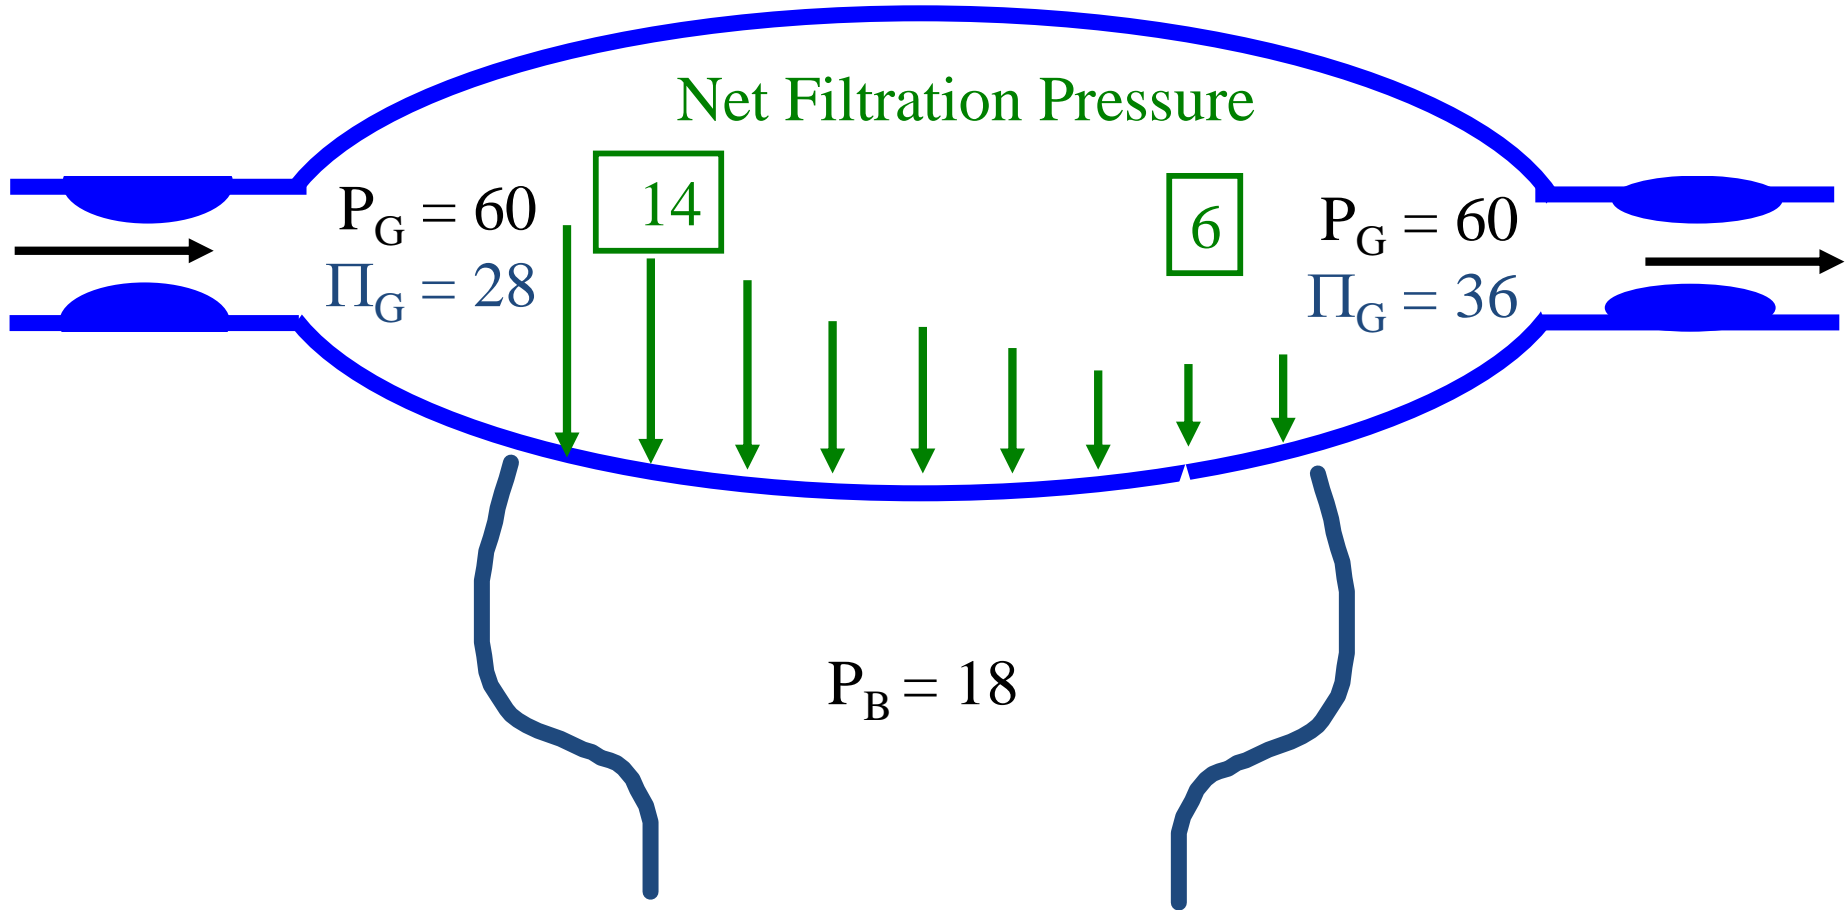

Figure 26-14

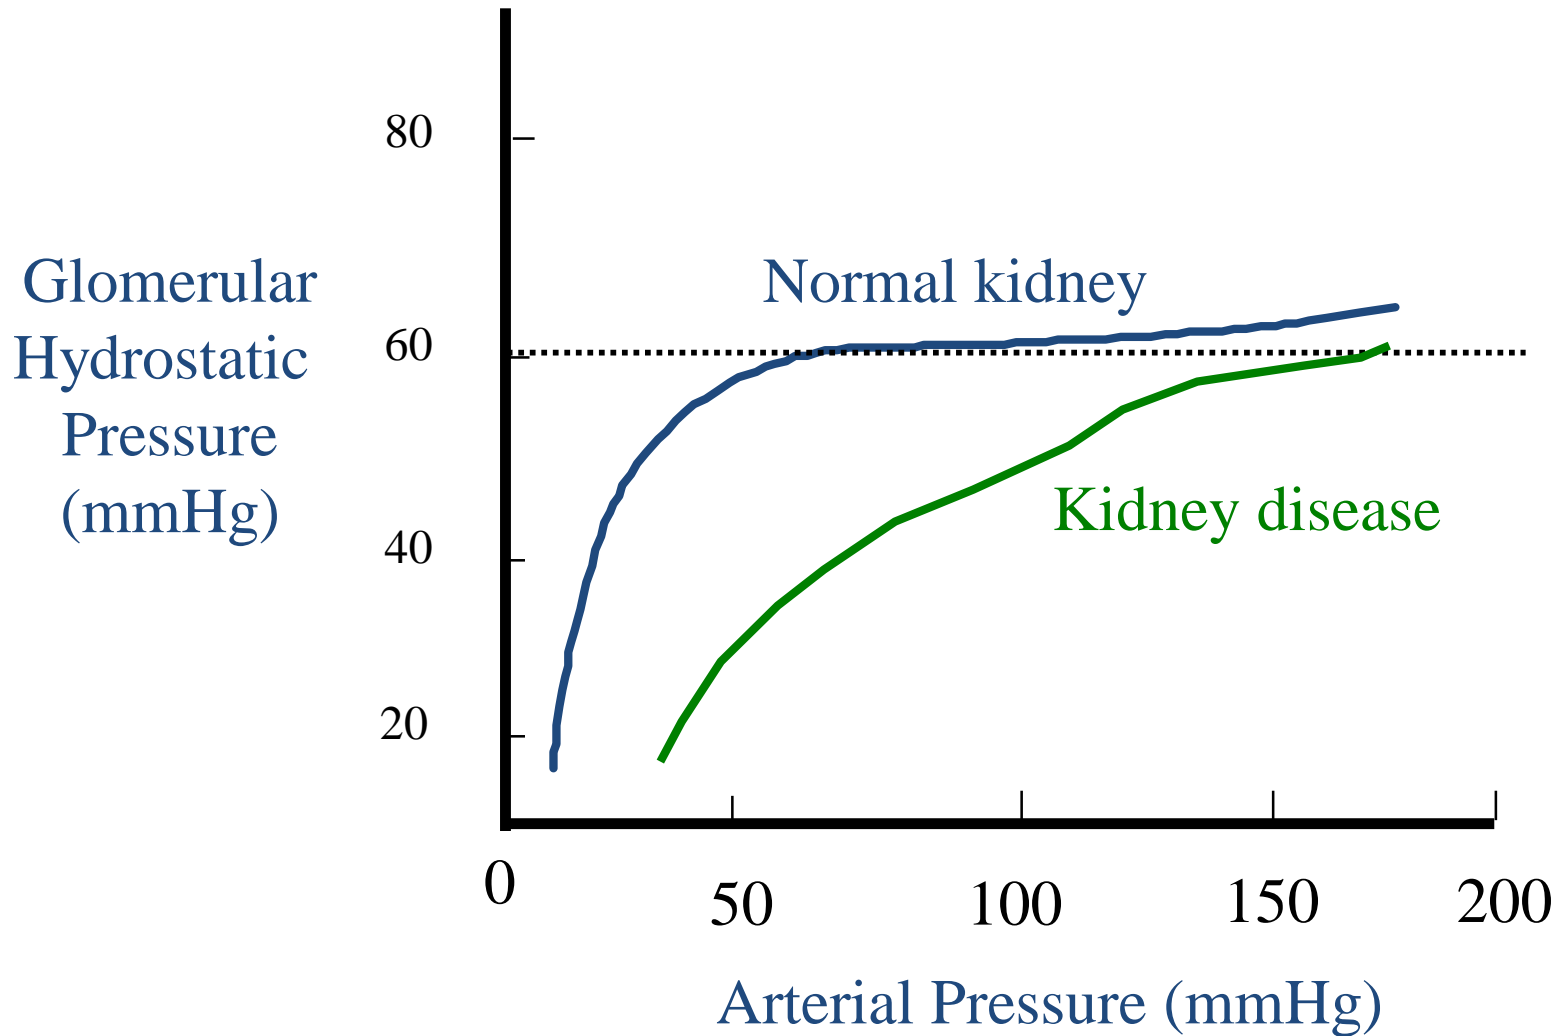

Microalbuminuria

- **Definition:** urine excretion of > 30 but < 150 mg albumin per day
- **Causes:** early diabetes, hypertension, glomerular hyperfiltration

Prognostic Value: diabetic patients with microalbuminuria are 10-20 fold more likely to develop persistent proteinuria

Glomerular Hydrostatic Pressure (P_G)

- Is the determinant of GFR most subject to physiological control
- Factors that influence P_G
 - arterial pressure (effect is buffered by autoregulation)
 - afferent arteriolar resistance
 - efferent arteriolar resistance

Autoregulation of renal blood flow and GFR but not urine flow

Figure 26-16

Effect of afferent and efferent arteriolar constriction on glomerular pressure

$\uparrow R_a \rightarrow \downarrow GFR + \downarrow \text{Renal}$

$\uparrow R_e \rightarrow \uparrow GFR + \downarrow \text{Renal}$

Effect of changes in afferent arteriolar or efferent arteriolar resistance

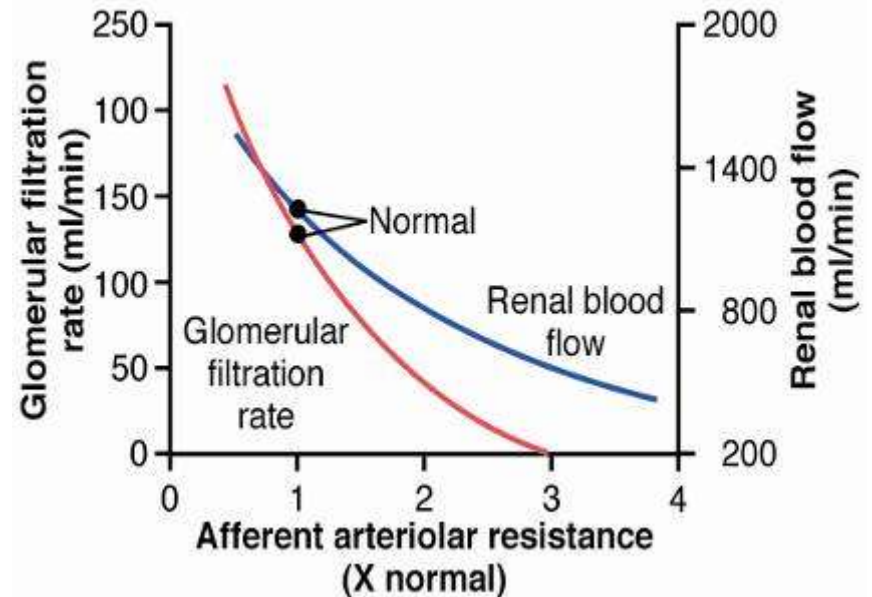

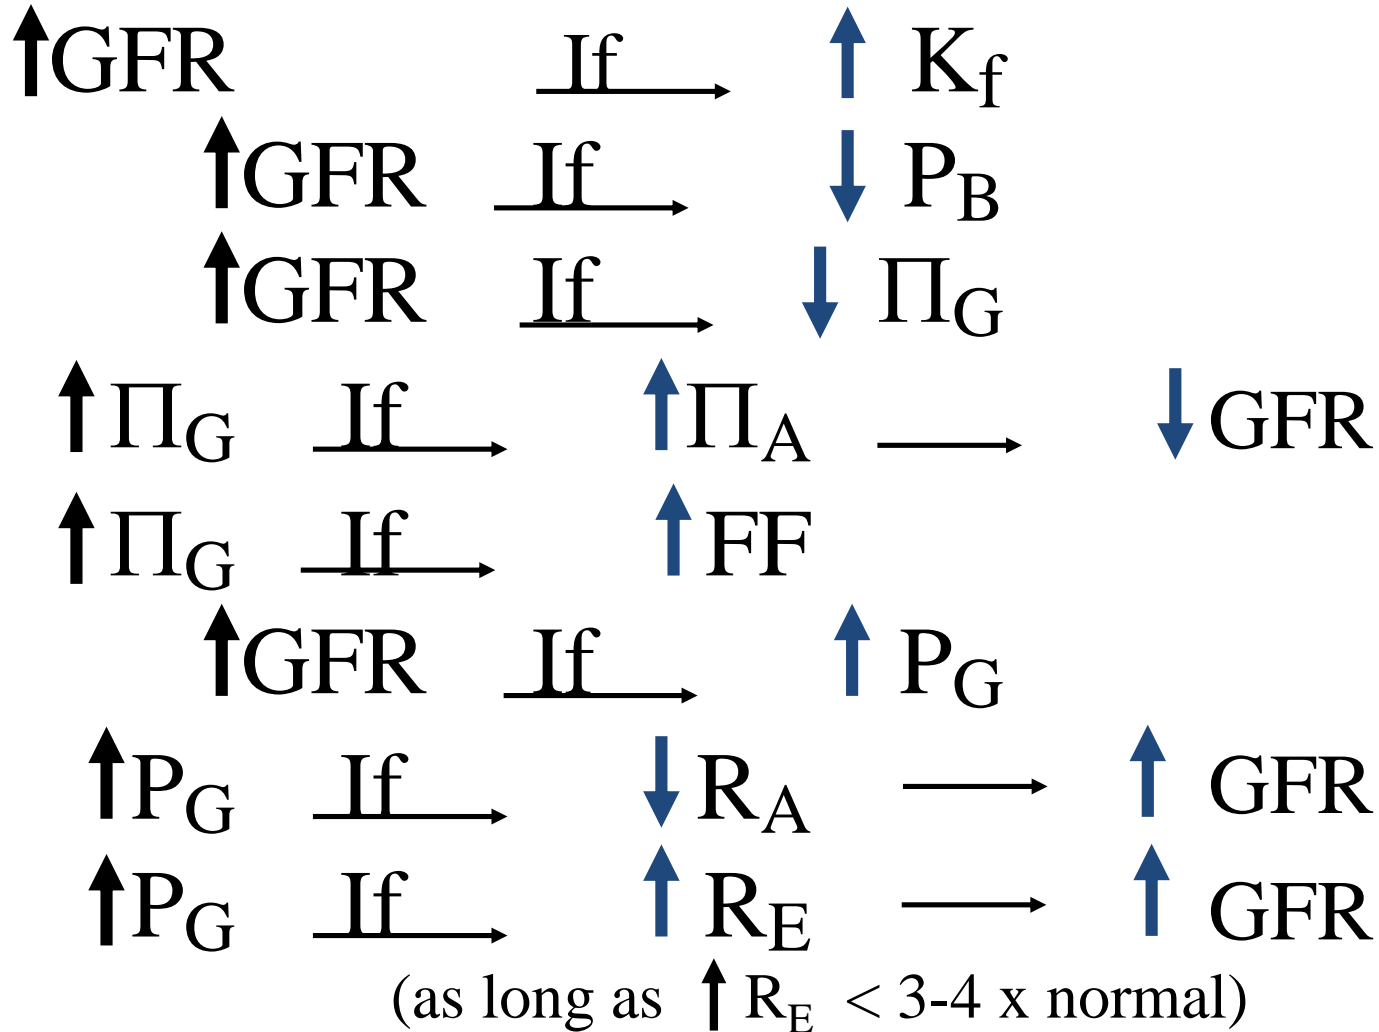

Figure 26-15

π_G determined by : $FF = GFR / RPF$

Summary of Determinants of GFR

Determinants of Renal Blood Flow (RBF)

$$\text{RBF} = \Delta P / R$$

ΔP = difference between renal artery pressure and renal vein pressure

R = total renal vascular resistance
 $= R_a + R_e + R_v$

= sum of all resistances in kidney vasculature

Renal blood flow

- High blood flow (~22 % of cardiac output)
- High blood flow needed for high GFR
- Oxygen and nutrients delivered to kidneys normally greatly exceeds their metabolic needs
- A large fraction of renal oxygen consumption is related to renal tubular sodium reabsorption

Renal oxygen consumption and sodium reabsorption

Figure 26-16
